

COMP219: Artificial Intelligence

Lecture 4: Intelligent Agents

Overview

- Last time
 - An introduction to Prolog
- Today:
 - A brief history of AI
 - Introduce 'agents'
 - Consider agent task environments
 - Consider agent program designs
- Learning outcome covered today:

Identify or describe the characteristics of **intelligent agents** and the **environments** that they can inhabit.

Brief History of AI

1943-56

- McCulloch & Pitts (1943)
 - artificial neural net - proved equivalent to Turing machine
- Shannon, Turing (1950)
 - Information theory
 - Turing Test
 - chess playing programs
- Marvin Minsky (1951)
 - first neural net computer - SNARC
- Dartmouth College (1956)
 - term “AI” coined by John McCarthy
 - Newell & Simon presented LOGIC THEORIST program

“Every aspect of learning or any other feature of intelligence can in principle be so precisely described that a machine can be made to simulate it”

Dartmouth manifesto

1956-70

- Programs written that could
 - plan, learn, play games, prove theorems, solve problems
- Major centres established
 - Minsky - MIT
 - McCarthy - Stanford
 - Newell & Simon - CMU
- Major feature of the period was *microworlds* - toy problem domains
 - Example: blocks world
 - “It’ll scale, honest. . . ”

1969: First International Joint Conference on Artificial Intelligence held

1970: First Issue of Artificial Intelligence journal

1970s

- 1970s period of recession for AI (an 'AI Winter')
 - (Lighthill report in UK) “formed the basis for the decision by the British government to end support for AI research in all but two universities [from AIAMA]”
- Techniques developed on microworlds would not scale
- Implications of complexity theory developed in late 1960s, early 1970s began to be appreciated
- Brute force techniques will not work
- Works in principle does not mean works in practice
- In US – foundational work on expert and knowledge based systems

1980s

- General purpose, brute force techniques don't work, so use *knowledge rich* solutions
- Early 1980s saw emergence of expert systems as systems capable of exploiting knowledge about tightly focused domains to solve problems normally considered the domain of experts
- Ed Feigenbaum's **knowledge principle**
- In UK Alvey programme (1984-89) revived funding and interest

1990s

- Many companies set up to commercialise expert systems technology went bust ('AI winter')
- 1990s: emphasis on understanding the interaction between *agents and environments*
- AI as *component*, rather than as end in itself

www.cis.upenn.edu

www.nasa.gov

2000s onwards

- Agents developed as a key technology for symbolic AI
 - www as a delivery mechanism
- Revival of sub symbolic AI and probability networks
- Advances in robotics, vision, etc.
- Fielded applications emerging...

Intelligent Agents

Intelligent Agents

- The intelligent entities that we engineer in AI are known as **agents**.
- A popular characterisation by Wooldridge and Jennings (1995) is:
“An **agent** is a computer system that is **situated** in some **environment**, and that is capable of **autonomous action** in this environment in order to meet its design objectives.”
- A collection of such agents situated together in an environment and capable of interacting in with one another is known as a ‘**multi-agent system**’.
- **Autonomy** is central to the notion of agency.

Intelligent Agents

- Capabilities that we would expect such intelligent agents to possess (again from Wooldridge and Jennings (1995)):
- **Reactivity**: Intelligent agents are able to perceive their environment, and respond in a timely fashion to changes that occur in it in order to satisfy their design objectives.
- **Proactiveness**: Intelligent agents are able to exhibit goal-directed behaviour by taking the initiative in order to satisfy their design objectives.
- **Social ability**: Intelligent agents are capable of interacting with other agents (and possibly humans) in order to satisfy their design objectives.

Intelligent Agents

Task Environments

- Agents are situated within **task environments**, which differ in accordance with the particular problem area that the agent is designed to address.
- When we design agents to solve particular problems, we must specify the task environment as fully as possible. Four elements to take into account:
- **PEAS** (from AIAMA):
 - **Performance measure**: the criteria by which we can measure the success of an agent's behaviour.
 - **Environment**: the external environment that the agent inhabits.
 - **Actuators**: the means by which the agent acts within its environment.
 - **Sensors**: the means by which the agent senses its environment.

Example

- Consider an agent used for medical diagnosis; Its PEAS description might be as follows:
- **Performance measure**: health of patient, costs of treatment.
- **Environment**: patient, hospital, staff.
- **Actuators**: display questions, tests, diagnoses and treatments.
- **Sensors**: keyboard entry of patient's symptoms, responses to questions and findings.

Exercise

Develop a PEAS description of the task environment for a mobile agent designed to roam the moon and gather rock samples.

Task Environments

- The properties of the task environment that the agent inhabits may differ greatly, depending upon the particular application area.
- Russell and Norvig have given a classification of the different types of **properties** of agent environments:
 - Fully observable vs partially observable
 - Deterministic vs stochastic
 - Episodic vs sequential
 - Static vs dynamic
 - Discrete vs continuous

Fully Observable vs Partially Observable

- **Fully observable** environment: one in which the agent can fully obtain complete, up-to-date info about the environment's state.
- Most moderately complex environments are **partially observable**.
- Fully observable environments are more convenient
 - agent does not need to maintain any internal state to keep track of the environment.
 - simpler to build agents for such environments.
- Fully observable env. examples: a crossword puzzle, the game of backgammon.
- Partially observable env. examples: the everyday physical world, the Internet, the card game poker.

Deterministic vs Stochastic

- **Deterministic** environment: one in which any action has a single guaranteed effect - there is no uncertainty about the state that will result from performing an action.
- This definition applies *from the point of view of the agent*.
- If the environment is deterministic except for the actions of other agents, the environment is said to be **strategic**.
- **Stochastic** environments present greater problems for the agent designer.
- Deterministic env. examples: a crossword puzzle, image analysis.
- Stochastic env. examples: medical diagnosis, the card game poker, the physical world.

Episodic vs Sequential

- **Episodic** environment: one where the performance of an agent is dependent on a number of discrete episodes, with no link between its performance in different scenarios.
- Episodic environments are simpler for agent developers
 - the agent can decide what action to perform based only on the current episode without having to reason about the interactions between this and future episodes.
- In **sequential** environments the current decision could affect all future decisions.
- Episodic env. examples: a mail sorting system, defect detection on an assembly line.
- Sequential env. examples: poker, a robot that delivers mail and coffee

Static vs Dynamic

- **Static** environment: one that can be assumed to remain unchanged whilst the agent is deliberating.
- **Dynamic** environment: one that has other processes operating on it, and hence changes whilst the agent is deliberating.
- Static environments are easier to deal with
 - the agent does not need to keep observing the environment whilst deciding how act, nor need it worry about time elapsing.
- Static env. examples: a crossword puzzle, the card game poker, the game of backgammon.
- Dynamic env. examples: medical diagnosis, the physical world.

Discrete vs Continuous

- **Discrete** environment: one that contains a fixed, finite number of distinct states.
- The distinction applies to the **state** of the environment, the way in which **time** is handled, the **percepts** and **actions** of the agent.
- **Continuous** environments provide greater challenges for agent designers.
- Discrete env. examples: a crossword puzzle, the game of chess.
- Continuous env. exmples: image analysis, medical diagnosis.

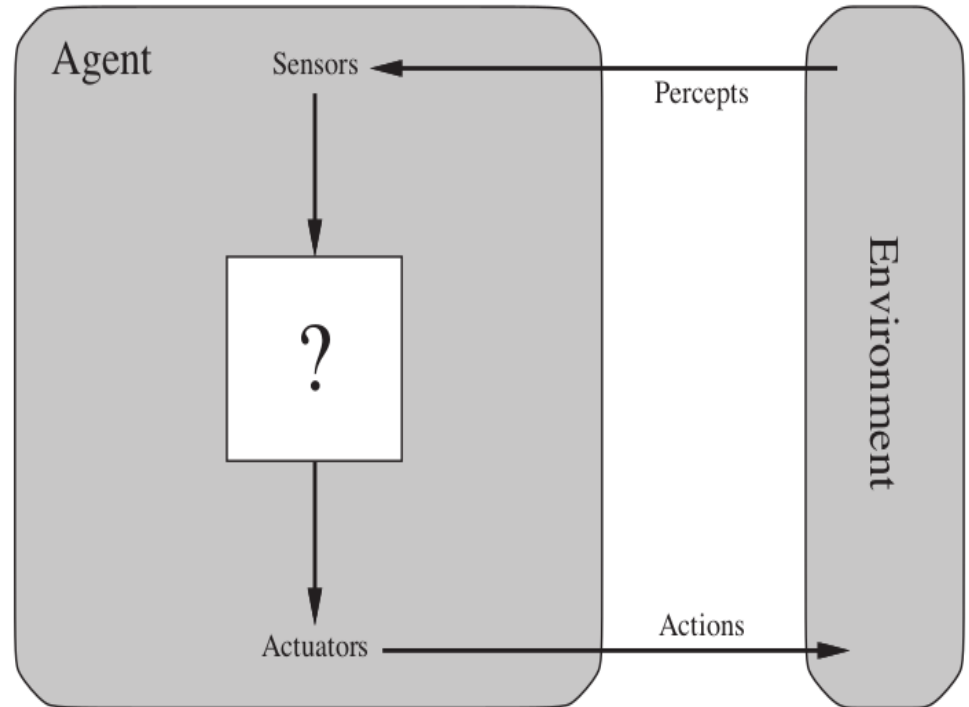

Exercise

Considering each of the previous characteristics, which apply to an automated agent designed to drive a taxi?

- Fully observable vs partially observable
- Deterministic vs stochastic
- Episodic vs sequential
- Static vs dynamic
- Discrete vs continuous

Agent Design

- 'Agent function'
 - math perspective
 - implemented by an **agent program**
- Agent = architecture + program

- Architecture: some computing device equipped with sensors and actuators
 - e.g., a mobile robot with sensors, a PC, etc.
- Most of AI focuses on the agent program

Agent Program Designs

- Four basic kinds of agent program are identified that embody the notions that underpin most intelligent systems (AIAMA):
 - 1) Simple reflex agents
 - 2) Model-based reflex agents
 - 3) Goal-based agents
 - 4) Utility-based agents
- The ability to learn improves the performance of all these agents.
 - Enables agents to operate in environments of ignorance.
 - Increases performance beyond the limitations of agents' current knowledge.

Simple Reflex Agents

- Simple reflex agents:
 - select actions to execute based upon the **current** percept.
 - Do not take the percept history into account.
 - E.g., implemented using condition-action rules.
 - Such agents are simple to implement, but of very limited intelligence.
 - Success of decision making seriously deteriorates with unobservability.

Model-Based Reflex Agents

- Last percept may not identify the exact **state of the environment**
- Model-based reflex agents:
 - use a **model** of the environment
 - to keep track of the current **state** of the world:
state \leftarrow Update(state, action, percept, model)
 - Requires knowledge
 - How the world changes independent of the agent's actions.
 - How the world changes due to the agent's actions.

Goal-Based Agents

- Goal-based agents: select actions to achieve **goals** (particular desirable states of the environment)
 - Knowledge of the current state does not automatically mean that the agent knows what to do:
 - long sequences of actions to achieve a goal...
 - Search and planning may be required.
 - Goal-based agents more flexible: easier to modify than reflex-based agents. (“Programming via goals”)

Utility-Based Agents

- Utility-based agents: use a **utility function** to compare the 'desirability' of different states that result from actions.
 - Many actions may satisfy a goal, but which is the most desirable?
- **Utility function**: maps a state (or sequence of states, and/or actions), onto a real number which represents 'usefulness' of the state to the agent.
 - Agent tries to maximise the value of its utility function.
- Enables:
 - Tradeoffs between competing goals.
 - Dealing with uncertainty
 - evaluate goal importance against likelihood of success.
 - Therefore can lead to higher quality behaviour than goal-based agents.

Summary

- Today
 - Intelligent agents
 - Task environments
 - PEAS description
 - Properties of environments
 - Agent program designs
